```

del x[1:3]; x[:2] = [4, 5, 6]

```
Set and mapping types (unordered):
             {'Fred', 'John'} set(('Fred', 'John'))
 frozenset frozenset(('Fred', 'John'))
 dict
             {'Fred': 123, 42: 'John'}
             dict([('Fred', 123), (42, 'John')])
             dict(Fred=123, John=42)
Immutable set methods and operations:
 intersection() symmetric difference() issubset()
 union()
                                          issuperset()
                   copy()
 difference()
                                          isdisjoint()
 \{1, 2\} \& \{2, 3\} == \{2\}
```

```
\{1, 2\} == \{2, 1\}
\{1, 2\} \mid \{2, 3\} == \{1, 2, 3\}
                                             \{1\} < \{1, 2\}
                                            \{1, 2\} \leftarrow \{1, 2\}
\{1, 2\} - \{2, 3\} == \{1\}
\{1, 2\} ^{2} \{2, 3\} == \{1, 3\}
```

Set mutation methods:

```
add()
                    intersection update()
        update()
pop()
        remove()
                    difference_update()
clear() discard()
                   symmetric difference update()
```

Mapping methods and operations:

```
get()
              keys()
                         pop()
                                     copy()
setdefault()
              values()
                         popitem()
                                     fromkeys()
update()
              items()
                         clear()
x = {'a': 1, 'b': 2}; x['d'] = 5
'b' in x == True;
                       x['a'] == 1; del x['b']
```

List and dict comprehensions:

```
[2 * i for i in range(3)] == [0, 2, 4]
{i: i ** 2 for i in range(3)}
        == \{0: 0, 1: 1, 2: 4\}
```

Functions

Simple function definition, takes an argument of any type:

```
def double(x):
                            double(2) == 4
    return x * 2
                        double('abc') == 'abcabc'
```

Function that does not explicitly return a value:

```
def idle(): pass
                               idle() == None
```

```
Function with optional arguments:
```

```
def multiply(x, y=2):
                                 multiply(3) == 6
    return x * y
                              multiply(3, 5) == 15
                            multiply(3, v=5) == 15
```

Classes

Simple class definition with attributes and constructor:

```
class Simple:
                                   obj = Simple(7)
   x = None
                                   obj.x == 7
   def __init__(self, x):
       self.x = x
```

Subclass which accesses a method of its Superclass:

```
obj = XY(7, 9)
class XY(Simple):
   v = None
                                 obi.x == 7
                                 obj.y == 9
   def init (self, x, y):
       super(). init (x)
       self.y = y
```

Class with a method that can be called on instances:

```
class CalcZ(XY):
                                  obi = CalcZ(7, 9)
                                  obj.do z() == 63
   def do z(self):
       return self.x * self.y
```

Class with an automatically computed attribute:

```
class AutoZ(XY):
                                  obj = AutoZ(7, 9)
   @property
                                  obj.z == 63
    def z(self):
        return self.x * self.y
```

This cheat sheet refers to Python 3.6:

https://docs.python.org/3.6/

Coding style conventions according to PEP8 https://python.org/dev/peps/pep-0008/

Python cheat sheet

Code structure

Grouping: Whitespace has meaning. Line breaks separate statements, indentation creates logical blocks. Comments run from # to line break. Functional units go into modules (files) and packages (directories); each source file imports any modules it uses:

```
import math
for x in range(0, (4+1)*2): # numbers 0 <= x < 10
   y = math.sqrt(x)
    print('The square root of {} is {}'.format(
            x, y))
```

Variable names: May contain letters (unicode, case-sensitive), numerals

Logic and flow control

```
Conditions: compound statement or expression:
 if x < y:
                              print('ves'
      print(x)
                                    if some condition
                                    else 'no')
  elif x > y:
      print(y)
 else:
      print('equal')
Iteration: over sets or until termination:
 for name in ['John', 'Fred', 'Bob']:
      if name.startswith('F'):
          continue
      print(name)
 while input('Stop?') != 'stop':
      if 'x' in input('Do not type an x.'):
```

print('You typed an x.')

print('Loop finished without typing an x.')

break

else:
